

# **US Monetary Policy in a Globalized World**

Jesús Crespo Cuaresma (WU, WIC, IIASA, WIFO)

Gernot Doppelhofer (NHH)

Martin Feldkircher (OeNB)

Florian Huber (WU)

# Motivation

## 1 Globalization

- "... effective monetary policy making now requires taking into account a diverse set of global influences, many of which are not fully understood" Ben Bernanke, Stanford, 2007.
- "Monetary policy settings in major countries should continue to be carefully calibrated and clearly communicated, with cooperation among policymakers to help manage spillovers and spillbacks", IMF, 2014.

## 2 Time variation

- Broad consensus that US monetary policy transmission has changed over time (Sims and Zha, 2006)
- Primiceri (2005), Boivin (2006), Boivin et al. (2010) find evidence for gradual variation in parameters and volatility over time. What does this imply for spillovers?

# Agenda

- **Research questions:**
  - 1 Does the global economy respond to US monetary policy shocks?
  - 2 How does the reaction change over time?
  - 3 Do US interest rates react to foreign shocks?
- **Econometrics:** Time-varying parameter global vector autoregression with stochastic volatility (TVP-SV-GVAR).

# The linear GVAR model

Ingredients:  $N$  countries, a vector  $\mathbf{x}_{i,t}$  of macroeconomic time series, a link matrix  $\mathbf{W}_i$ ,  $\mathbf{x}_{i,t}^*$ , to approximate global factors

- 1 For each country  $i$ , specify a VARX\*(1,1) model:

$$\mathbf{x}_{i,t} = \underbrace{c_{i0} + c_{i1} \mathbf{t}}_{deterministics} + \underbrace{\Phi_{i1} \mathbf{x}_{i,t-1}}_{domestic} + \underbrace{\Lambda_{i0} \mathbf{x}_{i,t}^* + \Lambda_{i1} \mathbf{x}_{i,t-1}^*}_{international} + \varepsilon_{i,t}$$

where  $\mathbf{x}_{i,t}^* := \sum_{j=0}^N \omega_{ij} \mathbf{x}_{j,t}$  and  $\varepsilon_{i,t} \sim \mathcal{N}(0, \boldsymbol{\Sigma}_i)$

## Second Layer: Stacking the Single Models

- VARX(1,1):  $\mathbf{x}_{it} = \Phi_{i1}\mathbf{x}_{i,t-1} + \Lambda_{i0}\mathbf{x}_{it}^* + \Lambda_{i1}\mathbf{x}_{i,t-1}^* + \varepsilon_{it}$
- Use link matrix  $\mathcal{W}_i$  and selection matrix  $S_i$

$$S_i \mathbf{x}_t = \Phi_{i1} S_i \mathbf{x}_{t-1} + \Lambda_{i0} \mathcal{W}_i \mathbf{x}_t + \Lambda_{i1} \mathcal{W}_i \mathbf{x}_{t-1} + \varepsilon_{it}$$

$$\underbrace{(S_i - \Lambda_{i0} \mathcal{W}_i)}_{G_i} \mathbf{x}_t = \underbrace{(\Phi_{i1} S_i + \Lambda_{i1} \mathcal{W}_i)}_{H_i} \mathbf{x}_{t-1} + \varepsilon_{it}$$

$$G_i \mathbf{x}_t = H_i \mathbf{x}_{t-1} + \varepsilon_{it}$$

- Stack all country-specific models

$$G \mathbf{x}_t = H \mathbf{x}_{t-1} + e_t$$

- The **GVAR** model

$$\mathbf{x}_t = \underbrace{F \mathbf{x}_{t-1}}_{F=G^{-1}H} + \underbrace{\tilde{e}_t}_{G^{-1}e_t}$$

# From linear to TVP GVARs: Road map

## The TVP-SV-GVAR model with a Cholesky structure

Estimate structural / Cholesky form of the model (Lopes et al., 2013)

- + equation-by-equation estimation, exploits parallel computing
- ⇒ allows estimation of medium- to large scale TVP-SV-VARs

## Bayesian estimation

- Specify law of motions and priors for all parameters

## Identification

- 1 Use a recursive structure to identify monetary policy (MP) shocks in the USA and in three regions.
- 2 Use generalized impulse response functions (GIRFs) to calculate further regional shocks.

# The observation equation of the TVP-GVAR

For country model  $i$  we specify

$$\mathbf{A}_{i0,t} \mathbf{x}_{i,t} = \sum_{p=1}^P \mathbf{B}_{ip,t} \mathbf{x}_{i,t-p} + \sum_{q=0}^Q \mathbf{\Lambda}_{iq,t} \mathbf{x}_{i,t-q}^* + \boldsymbol{\nu}_{it}, \quad (1)$$

- $\mathbf{A}_{i0,t}$  is a  $k_i \times k_i$  matrix of structural coefficients
- $\mathbf{B}_{ip,t}$  ( $p = 1, \dots, P$ ) is a  $k_i \times k_i$  matrix of coefficients associated with the lagged endogenous variables
- $\mathbf{\Lambda}_{iq,t}$  ( $q = 0, \dots, Q$ ) denotes a  $k_i \times k_i^*$  dimensional coefficient matrix corresponding to the  $k_i^*$  weakly exogenous variables in  $\mathbf{x}_{it}^*$
- $\boldsymbol{\nu}_{it} \sim \mathcal{N}(0, \mathbf{D}_t)$  is a heteroskedastic vector error term with  $\mathbf{D}_t = \text{diag}(\lambda_{i0,t}, \dots, \lambda_{ik_i,t})$

# The state equations of the TVP-SV-VAR

For country model  $i$  we have

$$\boldsymbol{a}_{i,t} = \boldsymbol{a}_{i,t-1} + \boldsymbol{\gamma}_{i,t} \quad \boldsymbol{\gamma}_{i,t} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{V}_i) \quad (2)$$

$$\text{vec}(\boldsymbol{\Psi}_{i,t}) = \text{vec}(\boldsymbol{\Psi}_{i,t-1}) + \boldsymbol{\eta}_{i,t} \quad \boldsymbol{\eta}_{i,t} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{S}_i) \quad (3)$$

$$h_{il,t} = \mu_{il} + \rho_{il}(h_{il,t-1} - \mu_{il}) + \nu_{il,t} \quad \nu_{il,t} \sim \mathcal{N}(0, \varsigma_{il}^2) \quad (4)$$

with  $\boldsymbol{a}_t$  collecting the free elements of  $\boldsymbol{A}_t$ , and  $\boldsymbol{\Psi}_{i,t}$  collecting the elements of  $\boldsymbol{B}_{ip,t}$  and  $\boldsymbol{\Lambda}_{iq,t}$ . Finally  $h_{il,t} = \log(\lambda_{il,t})$  denotes the log-volatility of the  $l$ th equation in country model  $i$ .

## Bayesian inference: Prior setup

Priors on the initial state:

$$\begin{aligned}\mathbf{a}_{i0} &\sim \mathcal{N}(\mathbf{0}, \underline{\mathbf{V}}_{ai}) \\ \text{vec}(\boldsymbol{\Psi}_{i0}) &\sim \mathcal{N}(\mathbf{0}, \underline{\mathbf{V}}_{\boldsymbol{\Psi}_i})\end{aligned}$$

with  $\underline{\mathbf{V}}_{ai}$  and  $\underline{\mathbf{V}}_{\boldsymbol{\Psi}_i}$  diagonal prior variance-covariance matrices.

Priors on the variances of the state equations,  $\mathbf{V}_i$  and  $\mathbf{S}_i$ :

$$\begin{aligned}\nu_{i,rr}^2 &\sim \mathcal{G}\left(\frac{1}{2}, \frac{1}{2B_\nu}\right), \quad r = 1, \dots, l_i \\ s_{i,jj}^2 &\sim \mathcal{G}\left(\frac{1}{2}, \frac{1}{2B_s}\right), \quad j = 1, \dots, K_i\end{aligned}$$

where  $B_s$  and  $B_\nu$  denote scalars that control the tightness of the prior and  $l_i = k_i(k_i - 1)/2$ .

## Bayesian inference: Prior setup II

Prior for the volatility equation:

Normal prior on  $\mu_{il}$ ,

$$\mu_{il} \sim \mathcal{N}(\underline{\mu}_i, V_{\mu_i}).$$

Beta prior on the persistence parameter  $\rho$ ,

$$\frac{\rho_{il} + 1}{2} \sim \text{Beta}(e_0, f_0),$$

Gamma prior on  $\varsigma_{il}$ ,

$$\varsigma_{il} \sim \mathcal{G}(0.5, 1/(2B_\sigma)).$$

# Bayesian inference: Estimation of country model $i$

```
MCMC=function(X){
```

```
  For equation  $l = 1, \dots, k_i$  {
```

```
    Initialize  $\mathbf{V}_{il}$ ,  $\mathbf{S}_{il}$  and  $\mathbf{h}_{il} = (h_{il,0}, \dots, h_{il,T})'$ 
```

```
    For irep =1, ..., ntot{
```

- 1 Sample  $\mathbf{a}_{il}^T = (\mathbf{a}_{il,0}, \dots, \mathbf{a}_{il,T})'$  and

$$\text{vec}(\boldsymbol{\Psi}_{il})^T = (\text{vec}(\boldsymbol{\Psi}_{il,0}), \dots, \text{vec}(\boldsymbol{\Psi}_{il,T}))'$$

using the Carter & Kohn (1994) algorithm

- 2 Sample the variances of Eqs. (2) and (3) using Gibbs steps by noting that the conditional posteriors are of generalized inverse Gaussian form

- 3 Sample  $\mathbf{h}_{il}^T = (h_{il,1}, \dots, h_{il,T})'$  through the algorithm put forth in Kastner & Fruehwirth-Schnatter (2014)

```
}
```

```
}
```

Collect the parameter draws for all  $k_i$  equations  
and construct the TVP-SV-VAR

```
}
```

Note that the first for-loop can easily be parallelized!

# Data & country coverage

## Country coverage (36 countries)

Western Europe: AT, BE, DE, ES, FI, FR, GR, IT, NL, PT,  
DK, GB, CH, NO, SE.

Other developed economies: AU, CA, JP, NZ, US.

Emerging Asia: CN, IN, ID, MY, KR, PH, SG, TH.

Latin America: AR, BR, CL, MX, PE.

Mid-East and Africa: TR, SA, ZA.

## Data (1979Q4-2013Q4)

$\Delta y_{it}$ : Real GDP growth.

$\Delta p_{it}$ : CPI inflation.

$\Delta e_{it}$ : Change in the real exchange rate vis-a-vis the US dollar.

$i_{it}$ : Short-term interest rate.

$s_{it}$ : Term spread.

$\Delta p_{oil t}$ : Change in oil price, endogenous in US model.

# Identification

- First, we assess US and regional monetary policy shocks by assuming the following ordering (Christiano et al., 1996, 1999):

$$x_{0t} = (\Delta p_{oil_t}, \Delta y_{0t}, \Delta p_{0t}, i_{0t}, s_{0t})'$$

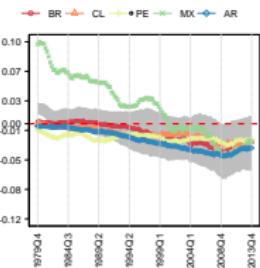

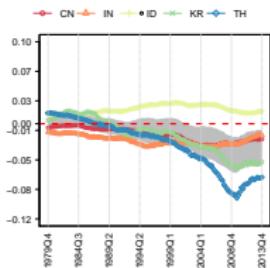

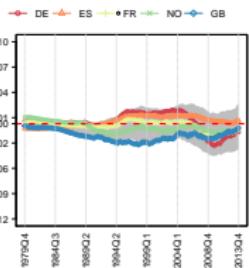

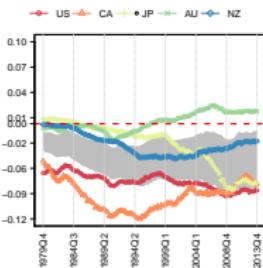

This is the same ordering as used in the estimation stage of the local TVP-SV models.

- Second we assess the US response to additional regional shocks using generalized impulse response functions:
  - 1 A positive shock to inflation by around one percentage point, on average, in Western Europe, Asia and Latin America,
  - 2 A negative output growth shock by around one percentage point, on average, in Western Europe, Asia and Latin America,
  - 3 A one percent real appreciation shock of the US dollar against currencies in Western Europe, Asia and Latin America.

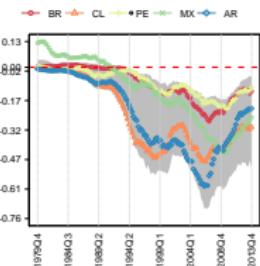

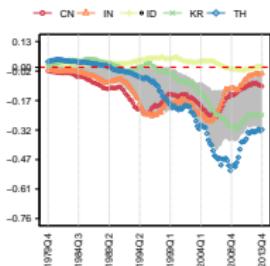

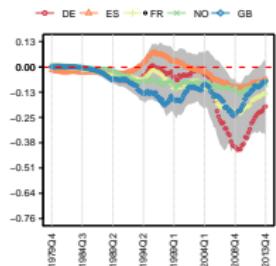

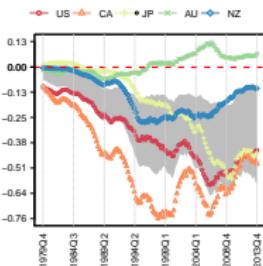

## RESULTS I: International responses to +100 bp US MP shock

# Real GDP growth (cumulative response)

$t = 1$

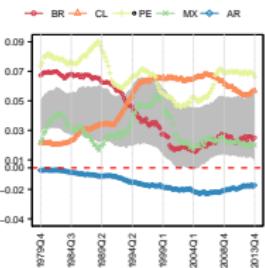

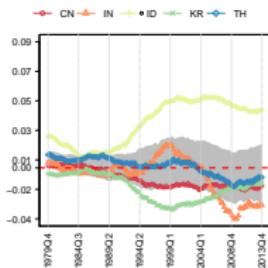

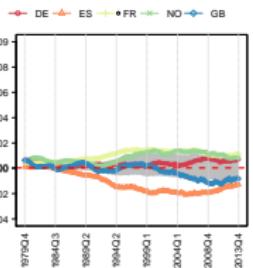

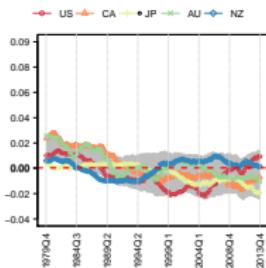

$t = 8$

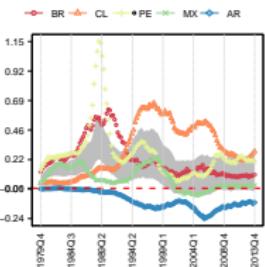

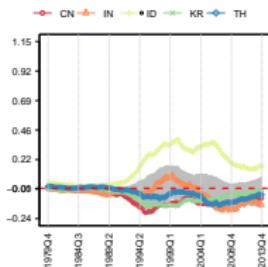

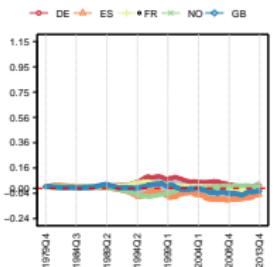

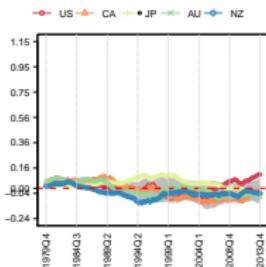

# Inflation (cumulative response)

$t = 1$

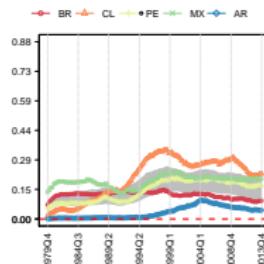

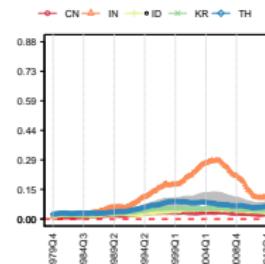

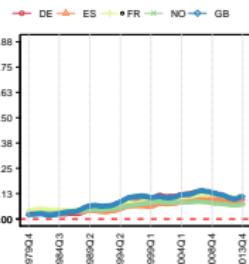

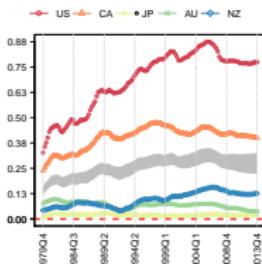

$t = 8$

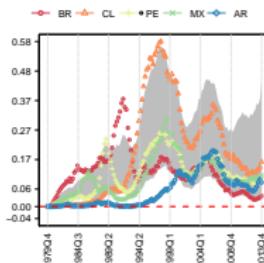

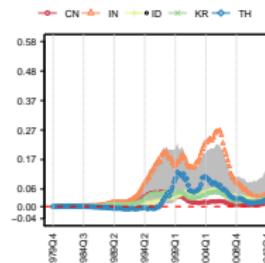

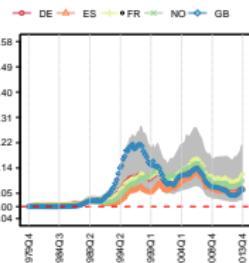

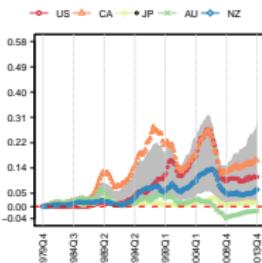

# Short-term interest rates

$t = 1$

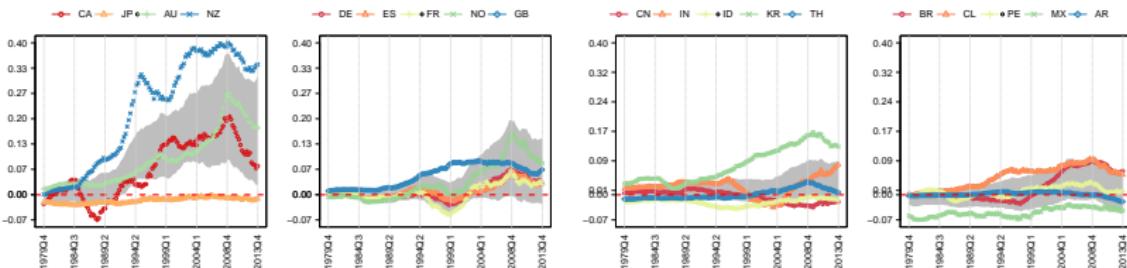

$t = 8$

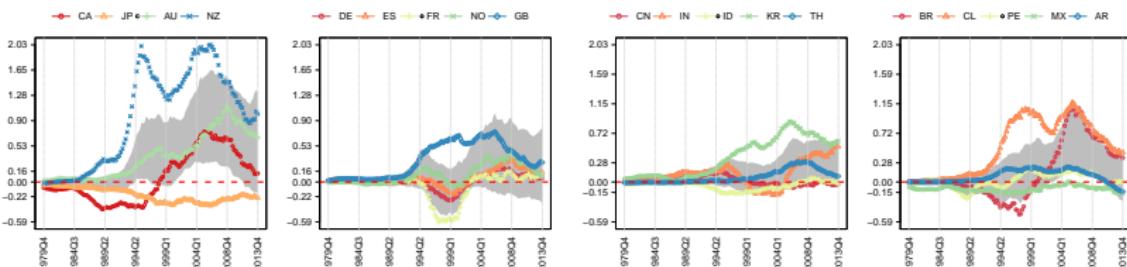

# International response of real exchange rate

+ denotes real appreciation of US dollar, cumulative response

$t = 1$

$t = 8$

## Remarks

A US monetary tightening leads to ...

- 1 A decrease international output (even after eight quarters)
- 2 A decrease in prices in the short-term (exception Latin America)
- 3 An increase of international interest rates.
- 4 A weakening of most currencies against the US dollar.

We also find

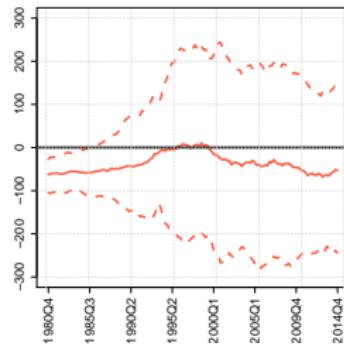

- Cross-country heterogeneity of spillovers, especially among emerging economies.
- Considerable time variation in international spillovers.

## RESULTS II: Responses of US interest rates to regional shocks

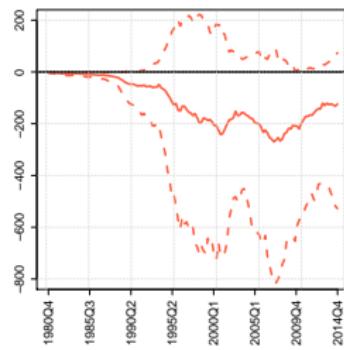

# US interest rate response to regional MP shocks

Western Europe

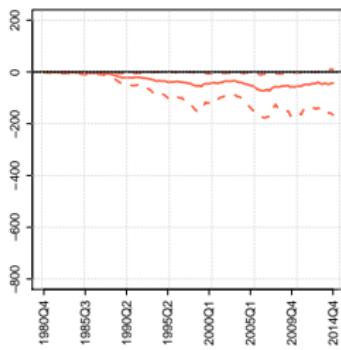

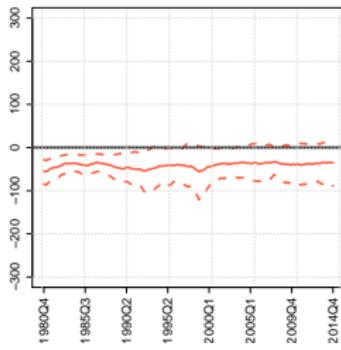

$t = 1$

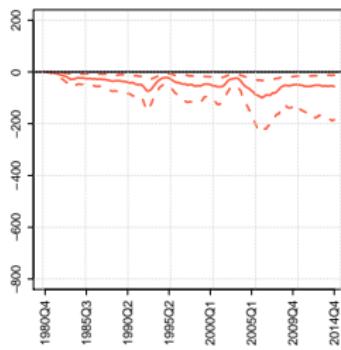

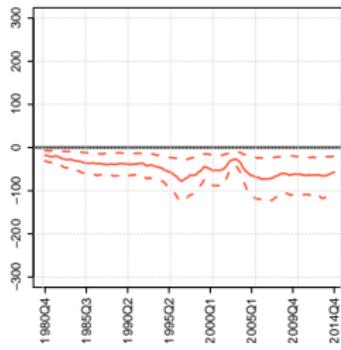

$t = 8$

Emerging Asia

Latin America

# US interest rate response to other regional shocks

**Notes:** The table presents the posterior distribution of generalized impulse response functions (GIRFs) associated with a regional rise in inflation, a reduction of regional real GDP growth and an appreciation of the US dollar against regional currency baskets. Responses are based on 1,500 posterior draws from a total chain of 30,000 iterations and in basis points. Responses for which credible sets do not include a zero value in bold.

# Conclusions I

- We developed a **new framework** for global macroeconomic analysis (TVP-SV-GVAR) which allows **for time-varying parameters and residual variances**
  
- A **US monetary policy tightening** triggers **significant spillovers**
  - Global real activity contracts and rather persistently.
  - International prices fall immediately, but adjust quickly.
  - Global nominal interest rates follow the US rate hike.
  - The US dollar tends to appreciate in real terms.
- **Cross-country heterogeneity:** countries highly integrated with USA (e.g., Canada), emerging economies (e.g., Brazil, Chile, India) show strongest response
- **Variation over time:** Strength of output and interest rate spillovers increased from the 1980s and peaked in 2008; afterwards extent of spillovers declined.

## Conclusions II

### 2 US interest rates respond to foreign regional shocks:

- In the medium term, **US short-term rates decrease** when either **foreign monetary policy is tightened or foreign real GDP growth decreases**.
- Domestic rates decreased to boost economic growth in the USA  $\Rightarrow$  **US rates do not follow international rates**
- **For other shocks, less compelling evidence** of US interest rate reaction.
- Exception: **shocks from Asia including China**. Here, **US rates also respond to an exchange rate shock** in the short-run and to **an inflation shock** in the medium-term.

Backup slides

## First Layer: Estimation of Country Models

- Each country is modeled as a country-specific VAR augmented with the foreign variables (VARX)

$$\mathbf{x}_{i,t} = \underbrace{c_{i0} + c_{i1} \mathbf{t}}_{deterministics} + \underbrace{\Phi_{i1} \mathbf{x}_{i,t-1}}_{domestic} + \underbrace{\Lambda_{i0} \mathbf{x}_{i,t}^* + \Lambda_{i1} \mathbf{x}_{i,t-1}^*}_{international} + \varepsilon_{i,t}$$

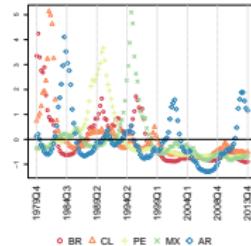

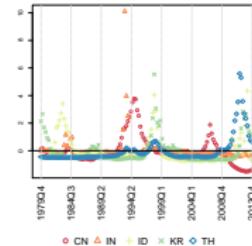

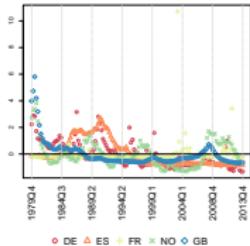

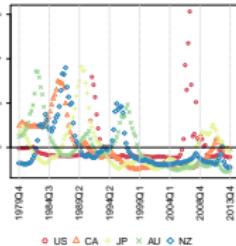

where  $\mathbf{x}_{i,t}^* := \sum_{j=0}^N \omega_{ij} \mathbf{x}_{j,t}$  and  $\varepsilon_{i,t} \sim \mathcal{N}(0, \boldsymbol{\Sigma}_i)$

## Second Layer: Stacking the Single Models

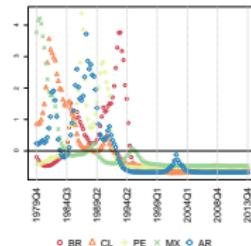

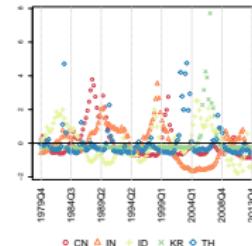

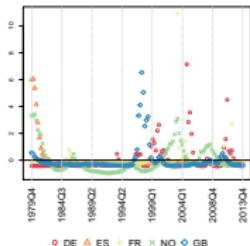

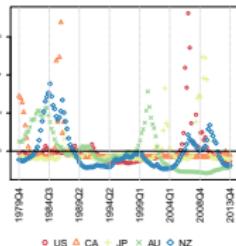

- After the country-by-country estimation of the VECMX we can proceed to the second step of the GVAR modelling strategy
  - 1 Recover the parameters of the VARX models
  - 2 Combine the VARX into a global model
- The resulting model will have the form of a standard VAR where all variables will be "endogenous"
- This is a purely mechanical step: **no estimation is involved!**

# Stochastic volatility over time

Real GDP growth

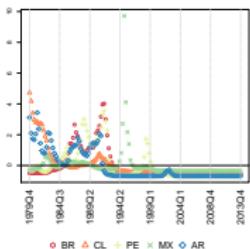

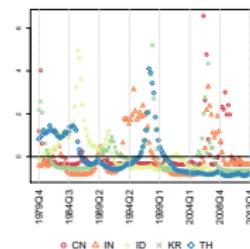

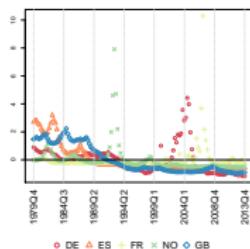

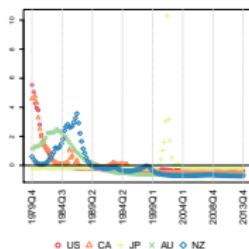

Inflation

# Stochastic volatility over time

## Short-term interest rate

## Real exchange rate
